Precast ... The Concrete Solution

The association of the manufactured concrete products industry.  
10333 North Meridian Street, Suite 272 | Indianapolis, Indiana 46290  
800-366-7731 | 317-571-0041 (fax) | [www.precast.org](http://www.precast.org)

## NOTES

1. This manual does not claim or imply that it addresses all safety-related issues, if any, associated with its use. Manufacture of concrete products may involve the use of hazardous materials, operations and equipment. It is the user's responsibility to determine appropriate safety, health and environmental practices and applicable regulatory requirements associated with the use of this manual and the manufacture of concrete products.
2. Use of this manual does not guarantee the proper function or performance of any product manufactured in accordance with the requirements contained in the manual. Routine conformance to the requirements of this manual should result in products of an acceptable quality according to current industry standards.

# INTRODUCTION

Precast concrete is ideally suited for utility, industrial and communications structures. A properly manufactured and installed precast concrete structure can last almost indefinitely. Precast concrete is inherently durable, highly impermeable and corrosion-resistant.

Utility, industrial and communications structures are an important part of the manufactured concrete products industry, and we must continue to provide project owners and end users with the best possible products at competitive prices. It is also important that those products contribute to the quality, timeliness and ease of installation of construction projects. The best practices outlined in this manual are intended to help manufacturers achieve these goals.

When properly designed and manufactured, precast concrete is capable of maintenance-free performance without the need for protective coatings, except in certain circumstances such as highly-corrosive environments. The “precast advantage” is further solidified through precast’s ease of installation and strength. Because precast concrete products typically are produced in a controlled environment, they exhibit high quality and uniformity. Adverse factors affecting quality which are typically found on job sites – variable temperature, uneven curing conditions, inconsistent material quality and craftsmanship – are significantly reduced in a plant environment.

High-quality concrete products are important for many applications, most notably for underground structures that must resist soil pressures and sustain surface loads. The controlled manufacturing environment in a precast concrete plant is ideal for the production of high-quality, durable concrete products.

This manual is intended to guide manufacturers in quality production processes for manufacturing utility vaults. The manual is not intended to be all inclusive and the recommendations are not intended to exclude any materials or techniques that would help achieve the goal of providing structurally sound, high quality products. Attention to detail, quality materials, proper training and a workforce dedicated to quality control will ensure that the utility vault meets or exceeds the expectations of contractors and end users.

# STRUCTURAL DESIGN

## Loading Conditions

A properly designed precast concrete utility vault must withstand a variety of loading conditions, which vary during manufacturing, installation, testing and service. These structures are designed to withstand loading conditions through rational mathematical design calculations, by proof-of-load testing or in accordance with ASTM C 857 "Standard Practice for Minimum Structural Design Loading for Underground Precast Concrete Utility Structures."

Consider the following in the design:

- Surface surcharge loads
- Concentrated wheel and other traffic loads
- Lateral loads
- Presumptive soil bearing capacity
- Buoyant forces
- Connections and penetrations
- Point loads

Precast concrete utility vaults should be designed according to one or more of the following industry codes and standards and as required by any regulatory groups with jurisdiction:

- ACI 318 – Building Code Requirements for Structural Concrete
- AASHTO – Specification for Highway Bridges
- ASTM C 857 – Standard Practice for Minimum Structural Design Loading for Underground Precast Concrete Utility Structures
- ASTM C 858 – Standard Specification for Underground Precast Concrete Utility Structures

The loading conditions illustrated in the diagram(s) should be analyzed and considered in the design of a utility structure.

The following design characteristics have a critical impact on the performance of utility structures.

## Concrete Thickness

The concrete thickness must be sufficient to meet minimum reinforcement cover requirements and withstand design loading conditions.

## Concrete Mix Design

Concrete must have a minimum compressive strength of 4,000 psi at 28 days. Consider methods to reduce permeability, improve durability and increase strength. Maintain a low water-cementitious ratio at or below 0.45.

## Reinforcement

Proper design and placement is critical to withstand the significant loads applied to utility vaults. Reinforcement must be sufficient for required strength and service conditions, including temperature and shrinkage effects. Control cracking by using multiple small-diameter steel bars rather than fewer large-diameter steel bars. Fiber reinforcement also helps to reduce cracking and may add some strength, but should not replace primary reinforcement. Welded-wire reinforcement can also be used, but particular attention should be paid to design and location. All reinforcement should meet applicable ASTM specifications.

# MATERIALS

The primary constituents of precast concrete are cement, fine and coarse aggregates, water and admixtures. The following discussion covers relevant factors in the selection and use of these fundamental materials.

## Cement

The majority of cement used in the manufactured concrete products industry is governed by ASTM C 150, “Standard Specification for Portland Cement.” The five primary types of ASTM C 150 cement are:

Type I	Normal
Type II	Moderate Sulfate Resistance
Type III	High Early Strength
Type IV	Low Heat of Hydration
Type V	High Sulfate Resistance

Select the cement type based on project specifications or individual characteristics which best fit the operation and regional conditions of each manufacturer. Note that certain types of cement may not be readily available in certain regions. Store cement in a manner that will prevent exposure to moisture or other contamination. Bulk cement should be stored in watertight bins or silos. If different types of cement are used at a facility, store each type in a separate bin or silo. Clearly identify delivery locations.

Design and maintain bin and silo compartments to discharge freely and independently into the weighing hopper. Cement in storage should be drawn down frequently to prevent undesirable caking. Stack bagged cement on pallets to permit proper air circulation and to avoid undesirable moisture and condensation. On a short-term basis (less than 90 days), stack the bags no more than 14 high. For long-term storage, do not exceed seven bags in height (or per manufacturer’s recommendations). Use the oldest stock first. Discard any cement with lumps that cannot be reduced by finger pressure.

## Aggregates

Ensure aggregates conform to the requirements of ASTM C33, “Standard Specification for Concrete Aggregates.” Evaluate the aggregates and maintain documentation at the plant for potential deleterious expansion due to alkali reactivity, unless the aggregates come from a state department of transportation-approved source. The maximum size of coarse aggregate should be as large as practical, but should not exceed 20 percent of the minimum thickness of the precast concrete utility vault or 75 percent of the clear cover between reinforcement and the surface of the vault. Larger maximum sizes of aggregate may be used if evidence shows that satisfactory concrete products can be manufactured.

Aggregates are an important constituent of precast concrete utility vaults. Nearly 75 percent of a precast concrete utility vault’s structure consist of coarse and fine aggregates.

The selection of appropriate aggregates is largely a regional concern. The selection process is based on using the best available clean, hard, durable aggregates and proper gradations. Aggregates should conform to ASTM C 33 – Standard Specification for Concrete Aggregates and ACI 318 – Building Code Requirements for Structural Concrete.

## Quality of Aggregates

Concrete is exposed to continuous moist and potentially corrosive conditions in underground applications. Consequently, two important selection parameters are the aggregate’s expansive properties when exposed to moisture and its porosity. It is important to specify a well-graded, sound, nonporous aggregate in accordance with ASTM C33 “Standard Specification for Concrete Aggregates.” This should be executed with limited amounts of materials that are deleteriously reactive with the alkalis in cement. When receiving aggregate from an area known to have potential problems with alkali-aggregate reaction, alkali-silica reaction or alkali-carbonate reaction, the aggregate supplier should provide sufficient laboratory data on the aggregate’s potential reactivity.

If the only available aggregates in your area have been found to cause excessive expansion of mortar or concrete, appropriate precautionary measures should be taken during the mix design process. The use of mineral admixtures, a low water-cement ratio or a low-alkali cement can all aid in controlling such expansive reactions. When using mineral admixtures or a low-alkali cement, trial batches should be tested to establish their viability in controlling the expansive reactions.

**Gradation of Aggregates**

Aggregate gradation influences both the economy and strength of a finished utility vault. The purpose of proper gradation is to produce concrete with a maximum density along with good workability to achieve sufficient strength.

Well-graded aggregates help improve workability, durability and strength of the concrete. Poorly graded or gap-graded aggregates rely on the use of excess mortar to fill voids between coarse aggregates, leading to potential durability problems. Concrete mixes containing rounded coarse aggregates tend to be easier to place and consolidate. However, crushed aggregates clearly are acceptable. The use of elongated, flat and flaky aggregates is discouraged. Gap-graded aggregates lacking intermediate sizes are also discouraged.

**Figure 2 — Poorly graded mix vs. Well-graded mix design**

*Porous concrete resulting from absence of fine materials. Arrows indicate water infiltration.*

*Inclusion of fine materials provides filling for spaces between coarse aggregates.*

**Aggregate Deleterious Substances**

Ensure all aggregates are free of deleterious substances, including:

- Substances that cause an adverse chemical reaction in fresh or hardened concrete
- Clay, dust and other surface-coating contaminants
- Structurally soft or weak particles

For good bond development, ensure aggregate surfaces are clean and free from excessive dust or clay particles. Excessive dust or clay particles typically are defined as material passing a #200 sieve, the limit of which is no more than 3 percent. Friable aggregates may fracture in the mixing and placement process, compromising the integrity of the hardened concrete product.

**Moisture Content of Aggregate**

The measurement of aggregate moisture content is important in the control of concrete workability, strength and quality. Aggregates – particularly fine aggregates (sands) – can collect considerable amounts of moisture on their surfaces. Fine aggregates can hold up to 10 percent moisture by weight; coarse aggregates can hold up to 3 percent.

Water on the surface of an aggregate that is not calculated into the mixture proportions will increase the water-cementitious ratio. The moisture content of aggregates will vary throughout a stockpile and will be affected by changes in weather conditions. Therefore, adjust mixture proportions as necessary throughout the production day to compensate for moisture content changes in the aggregate.

The following methods will increase the likelihood of uniform moisture content:

- Enclose storage of daily production quantities
- Store aggregates in horizontal layers
- Have at least two stockpiles
- Allow aggregate piles to drain before use
- Avoid the use of the bottom 12 inches of a stockpile
- Continuously sprinkle aggregate stock piles (climate dependent)
- Store entire stockpile indoors or under cover

Careful monitoring of aggregate moisture content during batching will reduce the need to add additional cement to offset excess water. This will maintain high-quality standards and save on expensive raw materials.

The plant should have a program in place that manages surface moisture content or accounts for moisture variation during batching.

## Handling and Storage of Aggregate

Aggregate handling is an important operation. Handle and store aggregates to prevent contamination and minimize segregation and degradation. Accurately graded coarse aggregate can segregate during a single improper stockpiling operation, so handling should be minimized to reduce the risk of particle size segregation. Also minimize the number of handling operations and material drop heights to avoid breakage.

The following methods can prevent segregation:

- Store aggregates on a clean, hard, well-drained base to prevent contamination. Bin separation walls should extend high enough to prevent overlapping and cross-contamination of different-sized aggregates.
- Avoid steep slopes in fine aggregate stockpiles. Fine aggregate stockpiles should not have slopes greater than the sand's angle of repose (i.e., natural slope, typically 1:1.5) to prevent unwanted segregation.
- Remove aggregates from a stockpile by working horizontally across the face of the pile. Avoid taking aggregate from the exact same location each time.

## Water

Water used in mixing concrete should meet the requirements of ASTM C 1602, "Standard Specification for Mixing Water Used in the Production of Hydraulic Cement Concrete." Avoid water containing deleterious amounts of oils, acids, alkalis, salts, organic material or other substances that may adversely affect the properties of fresh or hardened concrete.

## Chemical Admixtures

Commonly used chemical admixtures in precast concrete manufacturing include:

- Accelerating admixtures (ASTM C494, "Specification for Chemical Admixtures for Concrete")
- Air entrainment admixtures (ASTM C260, "Specification for Air-Entraining Admixtures for Concrete")
- Water-reducing admixtures (ASTM C494, "Specification for Chemical Admixtures for Concrete")
- High-range water-reducing admixtures or superplasticizers (ASTM C1017, "Chemical Admixtures for Use in Producing Flowing Concrete")

Store admixtures in a manner that avoids contamination, evaporation and damage. Protect liquid admixtures from freezing and extreme temperature changes, which could adversely affect their performance. It is also important to protect admixture batching components from dust and

temperature extremes. Ensure they are accessible for visual observation and periodic maintenance. Perform periodic recalibration of the batching system as recommended by the manufacturer or as required by local regulations.

Chemical admixture performance can vary. Exercise caution, especially when using new products. Test some trial batches and document the results before using a new admixture for production. Follow manufacturers' recommendations exactly. Carefully check admixtures for compatibility with the cement and any other admixtures used. Do not mix similar admixtures from different manufacturers without the manufacturer's agreement or testing to verify compatibility.

Additional guidelines for the use of admixtures are included in ACI 212.3, "Guide for Use of Admixtures in Concrete." Avoid accelerating admixtures that contain chlorides in order to prevent possible corrosion of reinforcing steel elements and other embedded metal objects.

## Supplementary Cementitious Materials (SCMs)

Supplementary Cementitious Materials are often incorporated into a concrete mix to reduce cement contents, improve workability, increase strength and enhance durability. The most common types of SCMs are fly ash, silica fume and ground granulated blast furnace slag (GGBFS) as know simply as slag. More than one SCM may be incorporated into a mix while various types of blended cements are also available. The following standards establish the minimum requirements for some of the common SCMs and blended cements.

- ASTM C595: Standard Specification for Blended Hydraulic Cements
- ASTM C618: Standard Specification for Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete
- ASTM C989: Standard Specification for Ground Granulated Blast-Furnace Slag for Use in Concrete and Mortars
- ASTM C1240: Standard Specification for Use of Silica Fume Used in Cementitious Mixtures

## Ready-Mixed Concrete

Verify that the ready-mixed concrete supplier is operating in accordance with ASTM C94, "Standard Specification for Ready-Mixed Concrete." Perform plastic concrete tests (slump, temperature, air content and density) at the plant prior to casting products. Record any added water on the delivery batch ticket for each truck and keep it on file.

# CONCRETE MIXTURE PROPORTIONING

Concrete mix design, also known as mix proportioning, is a broad subject – one that is specific to concrete in general and not necessarily to utility vaults in particular. This discussion will focus only on critical factors that pertain to high-quality precast concrete that is recommended when casting utility vaults.

Mix designs are selected based upon several necessary factors including permeability, consistency, workability, strength and durability. The elements necessary to achieve high-quality precast concrete include:

- Low water-cement ratio (less than 0.45)
- Minimum compressive strength of 4,000 psi at 28 days
- Use of quality aggregates
- Appropriate concrete consistency (concrete that can be readily placed by traditional methods; this is typically measured by slump)

High water-cement ratios lead to undesirable increased capillary porosity within the concrete. Capillary pores are voids resulting from the consumption and evaporation of water during the hydration or curing process. Enlarged and interconnected capillary voids serve as pathways for water and other contaminants to infiltrate the concrete system. Lower water-cement ratios result in smaller and fewer pores, reducing the concrete's permeability.

Aggregate quality and gradation have a tremendous impact on the concrete's overall quality. Mix designs with well-graded aggregates and sufficient quantities of fine aggregate have reduced water demands (i.e., lower water-cement ratios) while maintaining adequate workability and ease of placement.

Proper consistency of fresh concrete is a critical element in producing high-quality precast concrete. Fresh

concrete must be sufficiently plastic (flowable or deformable) to be properly placed, consolidated and finished. The size, shape and grading of aggregates, cement content, water-cement ratio and admixtures affect the workability of a mix.

Water-reducing admixtures and superplasticizers can greatly increase the workability of fresh concrete without changing the water-cement ratio. Experience has shown that concrete with low water-cement ratios (less than 0.45) can be properly placed and consolidated with the proper use of admixtures. However, air entrainment should be limited to keep the air content at a maximum of 7 percent.

The use of chemical admixtures for wet-cast concrete (such as air-entraining admixtures, water-reducing admixtures and superplasticizers) helps to attain workable concrete with a low water-cement ratio. Their use is particularly important, since most utility vaults require heavier reinforcing and have large penetrations that require special attention to ensure full consolidation. In certain circumstances, and where local regulations allow, properly designed and tested self-consolidating concrete (SCC) can be used to improve the likelihood of proper bond between concrete and reinforcement.

Air-entraining admixtures are designed to disperse microscopic air bubbles throughout the concrete's matrix to function as small "shock absorbers" during freeze-thaw cycles. The required air content for frost-resistant concrete is determined by the maximum aggregate size and severity of in-service exposure conditions (ACI 318). Air entrainment improves workability and reduces bleeding and segregation of fresh concrete while greatly improving the durability of hardened concrete.

# LIFTING INSERTS

Commercially manufactured lifting devices come furnished with documented and tested load ratings. Use the devices as prescribed by the manufacturer's specification sheets. Lifting devices should meet the minimum requirements of ASTM C857, "Standard Practice for Minimum Structural Design Loading for Underground Precast Concrete Utility Structures.

Lifting devices designed in the plant and not commercially manufactured must be load tested or evaluated by a professional engineer. In general, industry specifications require that lifting inserts have a minimum safety factor of three (ASTM C857) or four (29 CFR 1926.704, ANSI A10.9).

According to the "NPCA Quality Control Manual for Precast Concrete Products":

"All lifting devices and apparatus should meet OSHA requirements documented in 'Code of Federal Regulations' Title 29 Part 1926. Other applicable codes and standards are ANSI A10.9 and ASTM C 857.

A factor of safety of at least 4 is recommended for lifting devices. Manufacturers of standard lifting devices should provide test data to allow selection of appropriate loading.

Because of their brittle nature, reinforcing bars should not be used as lifting devices. Instead, smooth bars made of steel conforming to ASTM A36 can be used.

# COATINGS

Good concrete with a water-cement ratio less than 0.45 and a compressive strength greater than 4,000 psi is sufficient for utility vaults. Under normal conditions, there is no need for additional applications of asphalt, bituminous, epoxy or cementitious coatings. However, a protective exterior coating may be specified when a soil analysis indicates a potential for chemical attack.

# PRODUCTION PRACTICES

## Quality Control

All plants must have a quality control program and manual, including but not limited to the following:

- Documented mix designs
- Pre-pour inspection reports
- Form maintenance logs
- Post-pour inspection reports
- Performance and documentation of structural and watertightness testing discussed in this manual
- Plant quality control procedures
- Raw materials
- Production practices
- Concrete mixes
- Reinforcement fabrication and placement
- Concrete testing
- Storage and handling

Records of the above listed items should be available for review by appropriate agencies upon request.

Participation in the NPCA Plant Certification Program and future programs is recommended as an excellent way to ensure product quality. Use the NPCA “Quality Control Manual for Precast Concrete Products” as the basis for developing a strong quality control program.

## Forms

Forms must be in good condition. Frequent inspection intervals and regular maintenance ensure that forms are free of any damage that could cause concrete placement difficulties or dimensional problems with the finished product.

Use forms that prevent leakage of cement paste and are sufficiently rigid to withstand the vibrations encountered in the production process. Maintain forms properly, including cleaning after each use and inspection prior to each use, to ensure uniform concrete surfaces. Ensure forms are level and on a solid base.

# REINFORCEMENT

Fabrication drawings must be a part of every QC program. Fabrication drawings should detail the reinforcement requirements and all necessary information pertaining to the product prior to casting.

## Conventional Reinforcement

Fabricate reinforcing steel cages by tying or welding the bars, wires or welded wire reinforcement into rigid structures. The reinforcing steel cages should conform to the tolerances defined on the fabrication drawings. If not stated, minimum bend diameters on reinforcement should meet the requirements set forth in ACI 318, as defined in Table 1. Make all bends while the reinforcement is cold. The minimum bend diameter for concrete reinforcing welded wire reinforcement is  $4d_b$ .

**Table 1: Concrete Reinforcing Steel**

ASTM A615 and A706 Inch-Pound Bar Sizes	Minimum Bend Diameter	ASTM A615 and A706 Soft Metric Bar Sizes
# 3 through # 8	$6d_b$	# 10 through # 25
# 9, # 10 and # 11	$8d_b$	# 29, # 32 and # 36
# 14 and # 18	$10d_b$	# 43 and # 57

$d_b$  = nominal diameter (inch or mm) of bar

Weld reinforcement (including tack welding) in accordance with AWS D1.4, “Structural Welding Code, Reinforcing Steel.” This code requires either special preheat requirements (when required) or weldable grade reinforcement as defined by ASTM A706, “Specification for Low-Alloy Steel Deformed and Plain Bars for Concrete Reinforcement,” for any welding of reinforcing steel, including tack welds. Take special care to avoid undercutting or burning through the reinforcing steel.

Conventional reinforcement (ASTM A615, “Specification for Deformed and Plain Billet-Steel Bars for Concrete Reinforcement”) is produced from recycled metals that have higher carbon contents and are likely to become brittle if improperly welded. A brittle weld is a weak link, which can compromise the structural integrity of the finished product. ASTM A615/615M states: “Welding of material in this specification should be approached with caution since no specific provisions have been included to enhance the weldability. When the reinforcing steel is to be welded, a welding procedure suitable for the chemical composition and intended use or service should be used.”

Ensure lap splices for steel reinforcement (rebar and welded-wire reinforcement) meet the requirements of ACI 318. Adequate development length is required to develop the design strength of the reinforcement at a critical section. A qualified engineer should determine development length and clearly indicate it on shop drawings.

Reinforcement steel should be free of loose rust, dirt and form release agent. Cut, bend and splice reinforcing steel in accordance with fabrication drawings and applicable industry standards. Inspect reinforcing cages for size, spacing, proper bends and length. Secure the reinforcing cage in the form so that shifting will not occur during casting. Use only chairs, wheels and spacers made of noncorrosive materials.

It is important to place and hold reinforcement in position as shown in the fabrication drawings. A maximum recommended placement tolerance for the depth of reinforcement is  $+1/4$  inch (ACI 318). As a general rule the variation in spacing between bars should not exceed more than  $1/12$  of the designed bar spacing nor exceed 1.5 inch in variation, except for welded wire mesh conforming to Specifications A185 or A497. The recommended minimum concrete cover over reinforcing steel is  $3/4$  inch (ASTM C858).

## Fiber Reinforcement

Data must be available to show conclusively that the type, brand, quality and quantity of fibers to be included in the concrete mix are not detrimental to the concrete or to the precast concrete product. Fiber reinforced concrete must conform to ASTM C1116, “Standard Specification for Fiber-Reinforced Concrete and Shotcrete” (Type I or Type III). The two most popular types of fibers are synthetic and steel fibers. Steel fibers must conform to ASTM A820, “Specification for Steel Fibers for Fiber-Reinforced Concrete.” Do not use fibers as a replacement for primary structural reinforcing steel. In general, fibers will not increase the compressive or flexural strength of concrete.

Synthetic microfibers in concrete typically reduce plastic shrinkage cracks and improve impact resistance.

They can help reduce chipping when products are stripped. Typical dosage rates will vary from 0.5 to 2.0 lbs/yd<sup>3</sup>. Synthetic macrofibers and steel fibers may replace secondary reinforcement to provide equivalent bending stress and strength when compared with welded wire reinforcement and light-gauge steel reinforcement. Typical dosage rates for synthetic macrofibers vary from 3.0 to 20 lbs/yd<sup>3</sup>. Steel fiber dosage rates may vary from 20 to 60 lbs/yd<sup>3</sup>. Fibers must be approved by a regulatory agency or specifying engineer prior to concrete placement.

Design the concrete mix so that the mix is workable and the fibers are evenly distributed. Chemical admixtures or adjustments to the concrete mixture design may be necessary to achieve proper consolidation and workability. It is important to adhere to the manufacturer’s safety precautions and to follow instructions when introducing the fibers into the mix.

## Embedded Items

Items such as plates and inserts must be held rigidly in place during casting. All embedded items should be resistant to corrosion. Special consideration should be given when welding operations are required.

## Pre-Pour Inspection

A typical pre-pour checklist, as illustrated on the next page, provides a means of documenting the required quality checks. A qualified individual should make inspections prior to each pour. Correct any deviations prior to the start of placement activities.

Pre-Pour Operations Include:

- Preparing and setting forms
- Positioning steel reinforcement according to structural design
- Placing blockouts
- Positioning embedded items

# CASTING CONCRETE

## Transporting Concrete

When transporting concrete from mixer to form, use any method that does not contaminate the concrete, cause delay in placing, or segregation. Concrete can be discharged directly from the mixer into the forms – ACI 304, “Guide for Measuring, Mixing, Transporting and Placing,” is a valuable reference.

## Placing Concrete

### Conventional Concrete

Keep the free fall of the concrete to a minimum and deposit as near to its final location as possible. Do not use vibration equipment to move fresh concrete laterally in the forms.

### Fiber Reinforced Concrete (FRC)

Follow the same practices as described for conventional concrete, but note that the workability of the FRC may be slightly reduced.

### Self-Consolidating Concrete (SCC)

Place self-consolidating concrete into itself at a constant pressure head from one end of the form, allowing air to escape as the concrete flows into and around steel reinforcement. Avoid placement practices that add additional energy to the mix and cause unwanted segregation, such as excessive vibration, increased pour heights or increased discharge rates.

## Consolidating Concrete

SCC generally requires minimal consolidation efforts. However, when using conventional concrete, consolidation operations are required to minimize segregation and honeycombing. Consolidation can be improved on particular molds by using vibrators with variable frequency and amplitude. Three types of vibration are prevalent in the precast industry:

Internal – stick vibrator

External – vibrator mounted on forms or set on a vibrating table

Surface – vibrator can be moved across the surface

Lower internal vibrators vertically and systematically into the concrete without force until the tip of the vibrator reaches the bottom of the form. When using internal vibrators, concrete should be placed in wall sections using lifts not exceeding two feet. Do not drag internal vibrators horizontally. Once consolidation is complete in one area, remove the vibrator vertically and move the vibrator to the next area. Regardless of the vibration method, ensure that the field of vibration overlaps with another insertion to best consolidate the concrete and minimize defects.

Some external vibrators are mounted on a piece of steel attached to the form. Position them to allow for overlap of vibration areas. Continue the vibration process until the product is completely consolidated. Vibration is considered complete when large bubbles (3/8” diameter or greater) no longer appear at the surface. Care should be taken to avoid overvibration, because segregation of the aggregate from the cement paste can result in lowering the concrete quality and strength.

## Finishing Unformed Surfaces

Each product is to be finished according to its individual specifications. If finishing techniques are not specified, take care to avoid floating either too early or for too long. Premature finishing can trap bleed water below the finished surface, creating a weak layer of concrete susceptible to freeze-thaw cycles and chemical attack. Finishing with a wood or magnesium float is recommended.

# CURING PROCEDURES

Two critical elements in curing concrete are maintaining correct moisture content and maintaining correct concrete temperature. Proper curing is important in developing strength, durability and chemical resistance and watertightness – all important considerations for underground utility vaults.

Note: Concrete temperature discussed in this manual refers to the temperature of the concrete itself, not the ambient temperature.

The nature of precast operations poses unique challenges to proper curing. To ensure cost-effective use of forms, precasters often strip the forms at the beginning of the next workday. That is an acceptable standard, according to ACI 308, “Standard Practice for Curing Concrete.” The time necessary to develop enough strength to strip the forms is highly dependent on ambient temperature in the casting area. The Portland Concrete Association (PCA) lists three methods of curing:

1. Maintaining water moisture by wetting (fogging, spraying, wet coverings, etc.)
2. Preventing the loss of water by sealing (plastic coverings or applying curing compounds)
3. Applying heat (often in conjunction with moisture, with heaters or live steam)

Choose the method(s) that best suit the particular production operation. All three are permissible, but preventing the loss of water (method 2) may be the simplest choice for utility vaults. Maintaining moisture requires constant wetting, which is labor intensive. Alternate wetting and drying can lead to problems with cracking. Steam curing can also be effective. Concrete temperatures should never exceed 150 F. Both of these techniques are described in ACI 308, “Standard Practice for Curing Concrete,” and the PCA publication “Design and Control of Concrete Mixtures.” Plastic coverings or membrane-forming curing compounds require less labor efforts and allow form stripping the next work day. There are some special considerations for both:

1. Plastic sheeting must comply with ASTM C171, “Standard Specification for Sheet Materials for Curing Concrete,” which specifies a minimum thickness of 4 mm and be either white or opaque in color. PCA states that other colors can be used depending on sun conditions and temperature. When using multiple sheets, overlap them by approximately 18 inches to prevent moisture loss.
2. Curing compounds can be applied when bleed water is no longer present on the surface. As with plastic, white-colored compounds might reflect sunlight better and limit temperature gain. Follow the manufacturer’s recommendations.

## Cold and Hot Weather Concreting

In hot and cold weather, special precautions are necessary.

**Cold Weather** — Hydration rates are slower during cold weather. Concrete temperatures below 50 F are considered unfavorable for pouring due to the extended time required for strength gain and the possibility of freezing. However, once concrete reaches a minimum strength of 500 psi (usually within 24 hours) freezing has a limited impact. Ideally, precast concrete operations should be performed in heated enclosures that will provide uniform heat to the products until they reach 500 psi. If necessary, heating the mixing water and/or aggregates can increase the concrete temperature. Do not heat water above 140 F, and do not use clumps of frozen aggregate and ice. ACI 306, “Cold Weather Concreting,” contains further recommendations on cold-weather concreting.

**Hot Weather** — High temperatures accelerate hydration. Do not allow fresh concrete temperature to exceed 90 F at time of placement. Keep the temperature of the concrete mix as low as possible using a variety of means, including:

- Shading the aggregate piles
- Wetting the aggregates (mix design must be adjusted to account for the additional water)
- Using chilled water

Note: During the curing process, ensure that the concrete temperature does not exceed 150 F. In all cases, protect freshly cast products from direct sunlight and drying wind. ACI 305, “Hot Weather Concreting,” contains further recommendations on hot-weather concreting.

# POST-POUR OPERATIONS

## Handling Equipment

Cranes, forklifts, hoists, chains, slings and other lifting equipment must be able to handle the weight of the product with ease and comply with federal and local safety requirements. Routine inspections of all handling equipment are necessary. Qualified personnel should make periodic maintenance and repairs as warranted. Tag all chains and slings with individual load capacity ratings. For U.S. plants, refer to the specific requirements of the Occupational Safety and Health Administration (OSHA). For Canadian plants, refer to the specific requirements of the Canadian Centre for Occupational Health and Safety (CCOHS).

## Stripping and Handling Products

**Minimum Strength Requirement** – Concrete must gain sufficient strength before stripping it from the forms. Due to the nature of the precast business, the American Concrete Institute recognizes that forms will usually be stripped the next workday. Under normal conditions (concrete temperature greater than 50° F), properly designed concrete can reach the minimum compressive strength for stripping within this time period. Periodic compressive strength testing of one-day or stripping strength cylinders is recommended to confirm that proper concrete strength is attained.

Handle recently poured and stripped products with care. Perform lifting and handling carefully and slowly to ensure that dynamic loads do not damage the tank. Always follow recognized safety guidelines.

**Product Damage During Stripping** – Inspect the product immediately after stripping to check for damage.

## Post-Pour Inspections

A post-pour inspection checklist, as illustrated, provides a method of identifying and communicating quality problems as they occur. It serves as a method of gathering data for identification of any trends that may be evident. After a utility vault is stripped from the form, it should be inspected for conformance with the fabrication drawings and any necessary repairs should be made. All products should be clearly labeled with the date of manufacturing and marked in accordance with ASTM C 858.

### POST-POUR CHECKLIST

# FINISHING AND REPAIRING CONCRETE

**Finished Formed Surfaces** – Formed surfaces must be relatively smooth and free of significant honeycombed areas, air voids and “bugholes.”

**Repairing Minor Defects** – Defects that do not impair the use or life of the product are considered minor or cosmetic and may be repaired in any manner that does not impair the product.

**Repairing Honeycombed Areas** – Remove all loose material from the damaged area. Cut back the damaged zone in horizontal or vertical planes deep enough to remove the damaged concrete. Coarse aggregate particles should break rather than merely dislodge when chipped. Use only materials that are specifically developed for concrete repair, and make repairs according to the manufacturers’ specifications.

**Repairing Major Defects** – Major defects are defined as those that impair the intended use or structural integrity of the product. If possible, repair products with major defects by using established repair and curing procedures only after a qualified person evaluates the feasibility of the repair.

## **Secondary Pours**

For products that require secondary pours, establish procedures to assure that the new concrete bonds adequately to the product and becomes an integral part of it. The surfaces of the product against which the secondary pour is to be made should be free of laitance, dirt, dust, grease or any other material that will tend to weaken the bond between the original and new concretes. If the surface is very smooth, roughen it to help promote a good bond. As a minimum, use a high-quality water stop, keyway and continuation of reinforcing between pours to ensure a watertight joint.

## **Cold Joints**

Cold joints require special care and, as a minimum, should include a high-quality water stop, bonding agent and continuation of reinforcing between pours.

## **Final Product Inspection**

Utility vaults should be visually checked for required supplementary items, embedded items and quality at the plant prior to shipping.

## **Product Shipment**

All vehicles used to transport products must be in good condition and capable of handling the product without causing damage. Utility vaults should be adequately cured as specified prior to shipment to a job site or distant storage areas. All products must be properly secured with appropriate blockage and either nylon straps or chains with guards as to avoid product damage during shipment. NPCA’s publication *Cargo Securement for the Precast Concrete Industry* outlines proper methods for securing product. It is recommended that the final inspection include checking these items.

# SEALS, FITTINGS AND JOINTS

Careful attention to joint details, sealing materials and penetration fittings are important to ensure quality utility vaults. Systems in areas of high water tables may require special methods for joint and penetration seal designs.

## Joint Designs

The most common joint designs are tongue-and-groove or lap joints.

For the manufacture of utility vaults, it is recommended that only interlocking joints be used. In cases of potentially significant frost heave, differential settlement and groundwater exposure, greater attention to joint design detail is needed. Mechanical fasteners or secondary pours for lids on bases may be necessary in areas with severe site conditions. The key to preventing most differential settlement is proper bedding preparation (especially compaction) of the site.

## Sealing Materials

High-quality, preformed flexible joint sealants can be used to achieve a dependable joint. Use only sealants that contain less than 3 percent volatiles as defined in ASTM D6 – Standard Test Method for Loss on Heating of Oil and Asphaltic Compounds.

The characteristics of a high-quality sealant include:

- Workability over a wide temperature range
- Adhesion to clean, dry surfaces
- Good performance over time (must not shrink, harden or oxidize)

It is important that all joints be properly cleaned and prepared, according to the sealant manufacturer's recommendations. Preformed flexible joint sealants must be sufficiently pliable to compress a minimum of 50 percent at the temperature during assembly. Utility vault sections sealed on site should not be backfilled until the sealant has settled.

Properly splice the sealant by one of the following methods:

- Overlap splice – Place one piece on top of the other and carefully mold together
- Side-by-side – Place in parallel and carefully mold the two pieces together

## Sealant Size

A critical factor when evaluating the sealing potential of a sealant is cross-sectional area. Cross-sectional area is defined as the geometric shape of the sealant (i.e., 0.75 inches high by 1.0 inches wide). Industry experience has shown that a sealant's cross-sectional height must be compressed a minimum of 30 percent to create a good seal; 50 percent compression is desirable.

## Connections and Hardware

The functionality of a utility vault is increased through the use of high quality ancillary components such as cable racking assemblies, pulling irons, conduit terminators and pipe supports.

Cable racking assemblies should be specified to match the characteristics of the type of cable to be supported. The assemblies and their hardware for attachment to the wall of the vault should be engineered to carry the anticipated weight of the supported cables.

Pulling irons should be structurally engineered to resist the anticipated cable pulling loads. Additionally, the pulling load placed upon the wall of the utility vault should be considered in the structural design calculations for the vault. Pulling irons should not be used for lifting and handling product.

Cable industry standards require a smooth or rolled edge for the cable to pass over as it leaves the conduit to enter the utility vault. End bells and conduit terminators that are cast into the wall of the precast concrete vault at the time of manufacture provide a quality labor saving method to terminate conduit. These items should be sized and located on the wall of the vault to match the duct bank configuration.

Utility vaults may be configured to accommodate the piping systems used for fluid conveyance. Integral concrete sleepers, thrust blocks and pipe support hardware may be cast into the vault. Boots and gaskets may be incorporated at pipe entrances to ensure watertightness and should be sized and located for the pipe being used.

Hardware should always meet specification requirements of the design engineer and the customer.

### **Access, Risers and Manholes**

All access risers and manholes must be structurally sound and watertight.

# INSTALLATION

Proper installation is absolutely critical for maintaining the inherent quality of plant-manufactured concrete products and should be performed in accordance with ASTM C 891 – Standard Practice for Installation of Underground Precast Concrete Utility Structures. Many of the problems experienced with troublesome utility vaults can be attributed to incorrect procedures during installation. In addition to damaging the structure, improper installation techniques can lead to safety hazards.

## Site Conditions

The installation site must be accessible to large, heavy trucks or cranes weighing up to 80,000 pounds. The construction area should be free of trees, branches, overhead wires or parts of buildings that could interfere with the delivery and installation of the utility vault. Most trucks require access within 3 to 8 feet of the excavation to be unloaded.

## Excavation

Prior to excavation, all buried utilities should be identified and located. OSHA regulations governing excavation work should be followed at all times; 29 CFR, Part 1926.650-652.

Excavations should be made with approximately 18 inches of clearance around the installed structure to allow room for adequate compaction. More space should be provided, as needed, if work other than installation is required. Excavations should be sloped to comply with all construction safety requirements.

## Bedding

Proper use of bedding material is important to ensure a long service life of the utility vault. Engineered bedding material should be used as necessary to provide a uniform bearing surface. A good base should ensure that the structure would not be subjected to adverse settlement. A minimum 4-inch-thick sand or granular bed overlaying a firm and uniform base is recommended unless otherwise specified. Utility vaults should not bear on large boulders or massive rock edges.

Sites with silty soils, high water tables or other “poor” bearing characteristics must have specially designed bedding and bearing surfaces. In the presence of high water tables, structures should be properly designed to resist flotation.

Proper compaction of the underlying soil and bedding is critical to ensure there is no differential settlement.

## Placement

Prior to placement in the excavation, the structure’s orientation should be confirmed. Inlet penetrations should be aligned in the proper direction and the bedding material should be checked. After placement, check to ensure that the structure is level.

## Lifting Devices

Verify lifting apparatus such as slings, lift bars, chains and hooks for capacity, and ensure an adequate safety factor for lifting and handling products. The capacity of commercial lifting devices must be marked on the devices.

All lifting devices and apparatus should meet OSHA requirements documented in “Code of Federal Regulations” Title 29 Part 1926. Other applicable codes and standards are ANSI A10.9 and ASTM C857, C890 and C913.

A factor of safety of at least 4 is recommended for lifting devices. Manufacturers of standard lifting devices should provide test data to allow selection of appropriate loading.

Because of their brittle nature, do not use reinforcing bars as lifting devices. Use smooth bars made of steel conforming to ASTM A36 instead.

A factor of safety of at least 5 is recommended for lifting apparatus, such as chains, slings, spreader beams, hooks and shackles.

## Backfilling

Backfill should be placed in uniform, mechanically compacted layers less than 24 inches thick. This fill should be equally and uniformly placed around the vault. Backfill should be free of any large stones (greater than 3 inches in diameter) or other debris. Each layer should be adequately compacted.

# GLOSSARY

**admixture** – a material other than water, aggregates, cement and fiber reinforcement, used as an ingredient of concrete, and added to the batch immediately before or during its mixing. Typically are liquid in composition.

**admixture, accelerating** – an admixture that accelerates the setting and early strength development of concrete.

**admixture, air-entraining** – an admixture that causes the development of a system of microscopic air bubbles in concrete, mortar or cement paste during mixing.

**admixture, mineral** – finely divided, powdered or pulverized materials added to concrete to improve or alter the properties of the plastic or hardened concrete.

**admixture, water-reducing** – admixture that either increases the slump of freshly mixed concrete without increasing the water content or that maintains the slump with a reduced amount of water due to factors other than air entrainment.

**aggregate** – granular material, such as sand, gravel, crushed stone or iron blast-furnace slag used with a cement medium to form hydraulic-cement concrete or mortar.

**aggregate, coarse** – generally pea-sized to 2 inches; aggregate of sufficient size to be predominately retained on a No. 4 sieve (4.75 mm).

**aggregate, fine** – general coarse sand to very fine; aggregate passing the 3/8 inch sieve (9.5 mm) and almost entirely passing a No. 4 sieve (4.75 mm) and predominately retained on the No. 200 sieve (75 mm).

**air content** – the volume of air voids in cement paste, mortar, or concrete, exclusive of pore space in aggregate particles, usually expressed as a percentage of total volume of the paste, mortar or concrete.

**air void** – a space in cement paste, mortar or concrete filled with air; an entrapped air void is characteristically 1 mm or more in width and irregular in shape; an entrained air void is typically between 10  $\mu$ m and 1,000  $\mu$ m in diameter and spherical in shape.

**alkali-aggregate reactivity (AAR)** – a chemical reaction that occurs between the alkalis (sodium and potassium) from portland cement or other sources and certain constituents of some aggregates; under certain conditions resulting in deleterious expansion of concrete or mortar; often known as alkali-silica reaction (ASR). Cement manufacturers often test aggregates for AAR as a service to their customers.

**ASTM** – ASTM International is a not-for-profit organization that provides a forum for producers, users, ultimate consumers and those having a general interest (government and academia) to meet and write standards for materials, products, systems and services.

**bedding material** – gravel, soil, sand or other material that serves as a bearing surface on which a structure rests and which carries the load transmitted to it.

**bleeding** – the separation of mixing water or its emergence from the surface of newly placed concrete, caused by the settlement of the solid materials.

**bonding agent** – a substance applied to a suitable substrate to create a bond between it and a succeeding layer, such as between a layer of hardened concrete and a layer of fresh concrete.

**cement, hydraulic** – a cement that sets and hardens by chemical interaction with water and is capable of doing so under water.

**cementitious material** – an inorganic material or mixture of inorganic materials that set and develop strength by chemical reaction with water by formation of hydrates.

- concrete** – a composite material that consists essentially of a binding medium within which are embedded particles of fragments of aggregate, usually a combination of fine aggregate and coarse aggregate; in portland-cement concrete, the binder is a mixture of portland cement and water.
- concrete, fresh** – concrete that possesses enough of its original workability so that it can be placed and consolidated by the intended methods.
- compressive strength** – measured maximum resistance of a concrete or mortar specimen to axial compressive loading; expressed as a force per unit cross-sectional area; or the specified resistance used in design calculations.
- consistency** – the relative mobility or ability of freshly mixed concrete to flow; it is usually measured by the slump test.
- consolidation** – the process of inducing a closer arrangement of the solid particles in freshly mixed concrete during placement by the reduction of voids, usually accomplished by vibration, centrifugation, rodding, tamping or some combination of these actions. Consolidation facilitates the release of entrapped air; as concrete subsides, large air voids between coarse aggregate particles are filled with mortar.
- curing** – action taken to maintain moisture and temperature conditions in a freshly placed cementitious mixture to allow hydraulic cement hydration and (if applicable) pozzolanic reactions to occur so that the potential properties of the mixture may develop.
- curing compound** – a liquid that can be applied as a coating to the surface of newly placed concrete to retard the loss of water or to reflect heat so as to provide an opportunity for the concrete to develop its properties in a favorable temperature and moisture environment.
- dead load** – a constant load that in structures is due to the mass of the members, the supported structure, and permanent attachments or accessories.
- delayed ettringite formation (DEF)** – occurs at later ages (months to years) and the related heterogeneous expansion in hardened concrete can produce cracking and spalling. DEF is related to environmental or internal sulfate attack.
- deleterious substances** – materials present within or on aggregates that are harmful to hardened concrete, often in a subtle or unexpected way. More specifically, this may refer to one or more of the following: materials that may be detrimentally reactive with the alkalis in the cement (see alkali aggregate reactivity); clay lumps and friable particles; coal and lignite; etc.
- dry-cast (no-slump concrete)** – concrete of stiff or extremely dry consistency showing no measurable slump after removal of the slump cone.
- differential settlement** – the uneven sinking of material (usually gravel or sand) after placement.
- elongated aggregate** – a particle of aggregate where its length is significantly greater than its width.
- entrained air** – see air void; microscopic air bubbles intentionally incorporated in mortar or concrete during mixing, typically between 10  $\mu\text{m}$  and 1,000  $\mu\text{m}$  (1 mm) in diameter and spherical or nearly so.
- entrapped air** – see air void; air voids in concrete that are not purposely entrained and that are larger, mainly irregular in shape, and less useful than those of entrained air; typically greater than 1 mm in diameter and may be of various shapes.
- ettringite** – a mineral, high-sulfate calcium sulfoaluminate occurring in nature or formed by sulfate attack on mortar and concrete.

**float** – a tool, usually of wood, aluminum or magnesium, used in finishing operations to impart a relatively even but still open texture to an unformed fresh concrete surface.

**floating** – the operation of finishing a fresh concrete or mortar surface by use of a float, preceding troweling when that is to be the final finish.

**fly ash** – the finely divided residue transported by flue gases from the combustion of ground or powdered coal; often used as a supplementary cementitious material in concrete.

**forms (molds)** – a structure for the support of concrete while it is setting and gaining sufficient strength to be self-supporting.

**friable** – easily crumbled or pulverized, as it refers to aggregates.

**gap grading** – aggregate graded so that certain intermediate sizes are substantially absent (i.e., aggregate containing large and small particles with medium-size particles missing).

**gradation** – the particle-size distribution as determined by a sieve analysis (i.e., ASTM C 136); usually expressed in terms of cumulative percentages larger or smaller than each of a series of sizes (sieve openings) or the percentages between certain ranges of sizes (sieve openings).

**hydration** – formation of a compound by the combining of water with some other substance; in concrete, the chemical process between hydraulic cement and water.

**infiltration** – to cause (as a liquid) to permeate something by penetrating its pores or interstices.

**initial set** – a degree of stiffening of a mixture of cement and water less than final set, generally stated as an empirical value indicating the time in hours and minutes required for cement paste to stiffen sufficiently to resist to an established degree, the penetration of a weighted test needle; often performed on a sample of mortar sieved from a concrete sample.

**live load** – any load that is not permanently applied to a structure; including transitory loading such as water, vehicles and people.

**organic impurities (re: aggregate)** – extraneous and unwanted organic materials (twigs, soil, leaves, other debris) that are mixed in aggregates; these materials may have detrimental effects on concrete produced from such aggregates.

**OSHA** – Occupational Safety and Health Administration, U.S. Department of Labor.

**plastic concrete** – see concrete, fresh.

**portland cement** – a hydraulic cement produced by pulverizing portland-cement clinker, usually in combination with calcium sulfate.

**portland cement clinker** – a partially fused ceramic material consisting primarily of hydraulic calcium silicates and calcium aluminates.

**pozzolan** – a siliceous or siliceous and aluminous material that in itself possesses little or no cementitious value but will, in finely divided form and in the presence of moisture, chemically react with calcium hydroxide at ordinary temperatures to form compounds possessing cementitious properties.

**psf** – pounds per square foot

**psi** – pounds per square inch

- secondary pour** – a situation when a succeeding layer of concrete is placed on previously-placed hardened concrete.
- segregation** – the unintentional separation of the constituents of concrete or particles of an aggregate, resulting in nonuniform proportions in the mass.
- set** – the condition reached by a cement paste, mortar or concrete when it has lost plasticity to an arbitrary degree, usually measured in terms of resistance to penetration or deformation; initial set refers to first stiffening; final set refers to attainment of significant rigidity.
- silica fume** – very fine non-crystalline silica produced in electric arc furnaces as a byproduct of the production of elemental silicon or alloys containing silicon; also known as condensed silica fume and micro-silica. It is often used as an additive to concrete and can greatly increase the strength of a concrete mix.
- slump** – a measurement indicative of the consistency of fresh concrete. A sample of freshly mixed concrete is placed and compacted by rodding in a mold shaped as the frustum of a cone. The mold is raised, and the concrete is allowed to subside. The distance between the original and displaced position of the center of the top surface of the concrete is measured and reported as the slump of the concrete. Under laboratory conditions, with strict control of all concrete materials, the slump is generally found to increase proportionally with the water content of a given concrete mixture, and thus to be inversely related to concrete strength. Under field conditions, however, such a strength relationship is not clearly and consistently shown. Care should therefore be taken in relating slump results obtained under field conditions to strength. (ASTM C 143)
- specification** – an explicit set of requirements to be satisfied by a material, product, system or service that also indicates the procedures for determining whether each of the requirements is satisfied.
- standard** – as defined by ASTM, a document that has been developed and established within the consensus principles of the Society.
- superplasticizer** – see admixture, water-reducing. Superplasticizers are also known as high-range water-reducing admixtures.
- surcharge** – a surface load applied to the structure, transferred through the surrounding soil.
- trowelling** – smoothing and compacting the unformed surface of fresh concrete by strokes of a trowel.
- water-cement ratio** – the ratio of the mass of water, exclusive only of that absorbed by the aggregates, to the mass of portland cement in concrete, mortar or grout; stated as a decimal and abbreviated as w/c.
- waterstop** – a thin sheet of metal, rubber, plastic or other material inserted across a joint to obstruct the seepage of water through the joint.
- water table** – the upper limit of the portion of the ground wholly saturated with water.
- workability of concrete** – that property of freshly mixed concrete or mortar that determines the ease with which it can be mixed, placed, consolidated and finished to a homogenous condition.

This Best Practices Manual is subject to revision at any time by the NPCA Utility Vault Product Committee, which must review it at least every three years.

Special thanks are given to the Utility Vault Product Committee for updating/compiling this manual.
